## AC/DC Digital Power Controller for High Power Factor Dimmable LED Drivers

### 1.0 Features

- Isolated/non-isolated offline 120V<sub>AC</sub>/230V<sub>AC</sub> LED driver up to 25W output power
- Wide line frequency ranges (from 45Hz to 66Hz)
- Meets IEC61000-3-2 requirement
- Total harmonic distortion < 15% with PF > 0.95
- Wide dimmer compatibility
  - » Leading-edge dimmer
  - » Trailing-edge dimmer
  - » Digital dimmer
  - » Occupancy sensors and timers
- Under 20% output ripple current
- Wide dimming range from 1% to 100%
- Flickerless™ LED dimming
- Resonant control to achieve high efficiency (typical > 85% without dimmer)
- Over-temperature LED current foldback
- Small solution size
  - » Two-stage topology enables small-size input and output filter capacitors
  - » 200kHz maximum switching frequency enables small transformer
  - » Intelligent dimmer interface eliminates dedicated high-power bleeder
- Primary-side sensing eliminates the need for opto-isolator feedback
- Tight LED current regulation ( $\pm 5\%$ )
- Fast start-up (< 0.5s without dimmer)
- Supports hot-plug LED module (Zhaga)
- Compatible with NEMA SSL6 dimming curve standard
- Supports wide LED output voltage range
- Multiple protection features:
  - » LED open-circuit and short-circuit protection
  - » Over-current and over-temperature protection
  - » Current sense resistor short-circuit protection
  - » AC line over-voltage/-frequency protection

### 2.0 Description

The iW3617 is a two-stage, high-performance AC/DC offline power supply controller for dimmable LED luminaires. It applies advanced digital control technology to detect the dimmer type and phase, which provides dynamic impedance to interface the dimmer and control the LED brightness at the same time. The iW3617 uses iWatt's unique digital Flickerless™ technology to eliminate visible flicker in the entire dimming range and minimize low frequency output ripple current.

With advanced dimmer detection technology, the iW3617 can operate with most wall dimmers including leading-edge dimmers (R-type or R-L type) and trailing-edge dimmers (R-C type). In addition, the iW3617's cycle-by-cycle waveform analysis technology allows fast dimmer setting response. When no dimmer is on the line, the iW3617 optimizes the power factor and minimizes the current harmonic distortion to the AC line.

The iW3617 operates the main power converter that delivers constant current to the LED load in quasi-resonant mode to provide high power efficiency and minimize electro-magnetic interference (EMI). It uses iWatt's patented PrimAccurate™ primary-side sensing technology to achieve excellent LED current regulation under different AC line and LED load voltages, without using a secondary-side feedback circuit and eliminating the need for an opto-coupler.

The iW3617 minimizes the external components count by simplifying the EMI filter with iWatt's EZ-EMI® technology. The intelligent dimmer detection technology eliminates the need for a high-power bleeder. Additionally, the digital control loop of the iW3617 maintains stable overall operating conditions without the need for loop compensation components.

### 3.0 Applications

- Dimmable LED retrofit lamps up to 25W
- Dimmable LED ballast and luminaires up to 25W

### 4.0 Pinout Description

Pin #	Name	Type	Pin Description
1	BV <sub>SENSE</sub>	Analog Input	Boost inductor voltage feedback input
2	V <sub>IN</sub>	Analog Input	Rectified AC line voltage input
3	BI <sub>SENSE</sub>	Analog Input	Boost current sense input
4	B <sub>DRV</sub>	Output	Base drive output for boost BJT
5	CFG	Analog In/Out	Driver parameter configuration pin and auxiliary driver
6	ASU	Output	Active start-up and bleeder control
7	V <sub>CC</sub>	Power	Power supply for control logic and voltage sense for power-on reset circuit
8	PGND	Ground	Power ground
9	AGND	Ground	Signal ground. It should be connected to the power ground on PCB.
10	F <sub>DRV</sub>	Output	Gate drive output for flyback MOSFET
11	FI <sub>SENSE</sub>	Analog Input	Flyback current sense (used for cycle-by-cycle peak current control and limit)
12	FV <sub>SENSE</sub>	Analog Input	Flyback voltage sense (used for primary-side regulation and ZVS)
13	V <sub>T</sub>	Analog Input	External power limit shutdown control and external over-temperature power derating
14	V <sub>CB</sub>	Analog Input	Boost output voltage feedback input

### 5.0 Absolute Maximum Ratings

Absolute maximum ratings are the parameter values or ranges which can cause permanent damage if exceeded. For maximum safe operating conditions, refer to Electrical Characteristics in Section 6.0.

Parameter	Symbol	Value	Units
DC supply voltage range (pin 7, $I_{CC} = 20\text{mA max}$ )	$V_{CC}$	-0.3 to 18	V
DC supply current at $V_{CC}$ pin	$I_{CC}$	20	mA
$F_{DRV}$ output (pin 10)		-0.3 to 18	V
$B_{DRV}$ output (pin 4)		-0.3 to 4.0	V
CFG input (pin 5)		-0.3 to 4.0	V
CFG output (pin 5)		-0.3 to 18	V
$FV_{SENSE}$ input (pin 12, $I \leq 10\text{mA}$ )		-0.7 to 4.0	V
$BV_{SENSE}$ input (pin 1, $I \leq 3\text{mA}$ )		-0.7 to 4.0	V
$V_{IN}$ input (pin 2)		-0.3 to 18	V
$V_{CB}$ input (pin 14)		-0.3 to 18	V
$FI_{SENSE}$ input (pin 11)		-0.3 to 4.0	V
$BI_{SENSE}$ input (pin 3)		-0.3 to 4.0	V
ASU output (pin 6)		-0.3 to 18	V
$V_T$ input (pin 13)		-0.3 to 4.0	V
Power dissipation at $T_A \leq 25^\circ\text{C}$		900	mW
Maximum junction temperature	$T_{J\text{ MAX}}$	150	$^\circ\text{C}$
Storage temperature	$T_{STG}$	-65 to 150	$^\circ\text{C}$
Lead temperature during IR reflow for $\leq 15$ seconds	$T_{LEAD}$	260	$^\circ\text{C}$
Thermal Resistance Junction-to-PCB Board Surface Temperature	$\psi_{JB}$ (Note 1)	45	$^\circ\text{C/W}$
ESD rating per JEDEC JESD22-A114		2,000	V
Latch-up test per JEDEC 78		$\pm 100$	mA

#### Notes:

Note 1.  $\psi_{JB}$  [Psi Junction to Board] provides an estimation of the die junction temperature relative to the PCB surface temperature. This data is measured at the ground pins (pin 8 and pin 9) without using any thermal adhesives.

Figure 7.2 : Start-Up Threshold vs. Temperature

Figure 7.3 : % Deviation of Switching Frequency to Ideal Switching Frequency vs. Temperature

Figure 7.4 : Internal Reference vs. Temperature

### 9.0 Theory of Operation

#### 9.1 System Start Up

This section provides information about iW3617 system start up, which include the IC startup, wall dimmer detection, and the LED current soft start.

##### 9.1.1 IC Startup

When AC voltage is applied, the boost output capacitor in (C3 in Figure 11.1) is charged to the peak of line voltage. ASU pin is open by default so that ASU BJT (Q3 in Figure 11.1) is turned on and  $V_{CC}$  capacitors (C8 and C9 in Figure 11.1) is charged through ASU resistor (R9 in Figure 11.1) and ASU BJT. When the  $V_{CC}$  voltage reaches start-up threshold  $V_{CC(ST)}$ , the iW3617's control logic is activated and the IC starts up. The ASU pin is kept open and the ASU circuit continues charging  $V_{CC}$  until 50ms after the main flyback converter starts.

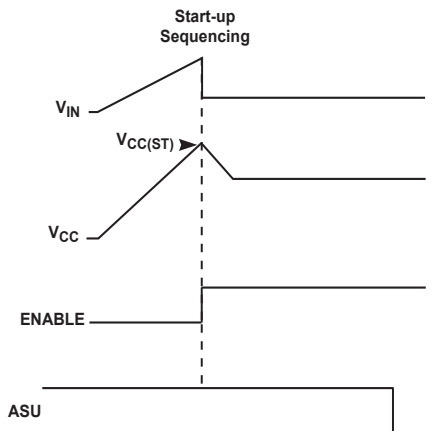

Figure 9.1 : Start-up Sequencing Diagram

##### 9.1.2 Wall Dimmer Detection

There are two basic categories of phase-cut wall dimmers: leading-edge dimmers and trailing-edge dimmers. If the AC voltage rises at the phase-cut edge, the dimmer is called leading-edge dimmer (shown in Figure 9.2). Otherwise it is called trailing-edge dimmer (shown in Figure 9.3). Normally speaking, leading-edge dimmer is TRIAC based (R-type, RL-type); trailing-edge dimmer is MOSFET or IGBT based (RC-type).

Figure 9.2 : Leading-Edge Wall Dimmer Waveforms

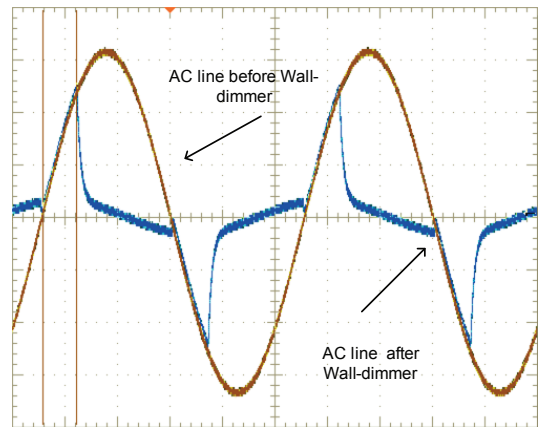

Figure 9.3 : Trailing-Edge Wall Dimmer Waveforms

The dimmer detection stage occurs in the iW3617 immediately after IC starts up. The iW3617 is driving the boost BJT (Q2 in Figure 11.1) constantly on to do current sinking during the wall dimmer detection. The purposes of current sinking at startup are:

- Calibrate the sinking current to 200mA to compensate for the BJT gain variation. This 200mA current sinking is used to latch the leading-edge dimmer during the phase-cut in normal operation.
- Place a low impedance resistance on the AC line to accurately detect whether a dimmer is connected and the type of dimmer connected.

The dimmer type can be determined by looking at the derivative of the input AC voltage. A large positive derivative value indicates a leading-edge dimmer. Otherwise, trailing-edge dimmer or no dimmer is detected.

# iW3617

## AC/DC Digital Power Controller for High Power Factor Dimmable LED Drivers

Once the dimmer type is determined, the iW3617 needs to qualify the AC input signal before delivering current to the LED load. If under any condition the iW3617 does not see the peak of  $V_{IN}$  signal above  $V_{IN\_ST(MIN)}$  for two consecutive AC half-cycles or the AC line frequency is out of range, the AC input signal is considered as unqualified. The iW3617 will continuously monitor the AC input signal until it sees a qualified AC input signal and then starts to deliver current to the LED load. Or if the  $V_{CC}$  drops under  $V_{CC(UVL)}$  in this process, the iW3617 will reset and the  $V_{CC}$  voltage will charge up again for a fresh start-up.

### 9.1.3 LED Current Soft-Start

After the iW3617 qualifies the AC input signal, the flyback converter will immediately start to deliver constant current to the LED load. A soft-start algorithm is applied to the flyback converter to gradually ramp up the LED current, thus reducing the stress on the LEDs. If no dimmer or a trailing-edge dimmer is detected, the output current will ramp up to the target current level within several AC half cycles. If a leading-edge dimmer is detected, the ramp up of the LED current is slower to avoid current over-shoot or under-shoot. This is because the leading-edge dimmer's phase conduction angle is usually not stable when the load on the dimmer is light.

If a dimmer is connected, the boost converter will start immediately into leading-edge or trailing-edge mode operation (refer to Section 9.31 and 9.32 for details) to interface the dimmer. If no dimmer is connected, the boost converter will start PFC operation (refer to Section 9.33 for details).

## 9.2 Phase Measurement and Dimming Curve

This section provides information about iW3617 phase measurement and dimming curve.

### 9.2.1 Phase Measurement

Dimmer phase conduction angle is measured every AC half cycle. Dimmer phase is determined by the time period that  $V_{IN}$  stays above the zero-crossing threshold ( $t_{CROSS}$ ) as shown in Figure 9.4. The threshold is 140mV.

Figure 9.4 : Dimmer Phase Measurement

And the dimmer phase ratio (D ratio) is calculated as:

$$\text{Dimmer Phase Ratio (D ratio)} = t_{CROSS} / t_{PERIOD} \quad (9.1)$$

The  $t_{PERIOD}$  is the period of AC half cycle, which is measured by the time span between the moments that  $V_{IN}$  rises above the 140mV reference in two consecutive AC half cycles. If the D ratio is above 90%, the iW3617 considers no dimmer is on the line.

### 9.2.2 Dimming Curve

The iW3617 dims the LED by reducing the output current to a certain percentage of the LED current level when there is no dimmer, which is called dimming percentage. A mapping between the D ratio and the dimming percentage is pre-determined in the iW3617. There are two different mapping options, or dimming curves, that can be selected with the CFG pin (refer to Section 9.5 for details). Both dimming curves fall within the limits of the NEMA SSL6 standard (as shown in Figure 10.6). The iW3617 updates the dimming percentage based on the D ratio measurement every AC half cycle to ensure fast dimmer response.

## 9.3 Dimmer Interface and Power Factor Correction Block Operation

This section provides information about iW3617 dimmer interface and power factor correction block's operation, which includes leading-edge dimmer mode, trailing-edge dimmer mode, no dimmer mode, and transition between these operation modes.

### 9.3.1 Leading-Edge Dimmer Mode

If a leading-edge dimmer is detected on the line, the boost converter is operated in leading-edge dimmer mode. This mode provides dynamic impedance matching for the leading-edge dimmers. The leading-edge mode operation can be split into five intervals, as shown in Figure 9.5.

Figure 9.5 : Leading-Edge Boost Mode Operation

During interval 0, the TRIAC in the leading-edge dimmer is turned off and the dimmer requires a low impedance load to charge its internal timing circuit. The boost BJT (Q2 in Figure 11.1) is driven in current sink mode to provide such low impedance load. When the TRIAC inside the dimmer is fired, the operation enters interval 1. Interval 1 is a short period of time after the TRIAC fires. The boost BJT is kept in current sink mode to provide 200mA latching current for the TRIAC. Then the operation enters interval 2. The boost BJT is in switching mode during interval 2. Interval 2 ends at 90° of the phase angle. During Interval 2, the iW3617 boosts the energy into the boost output capacitor and provides the holding current of the TRIAC at the same time. Interval 3 is a 400µs blanking time to ensure the TRIAC turns off after enough energy is boosted into the boost output capacitor. Then the operation enters interval 4 in which the boost BJT is in light duty-cycle switching mode to discharge the EMI filter capacitors of the LED driver.

### 9.3.2 Trailing-Edge Dimmer Mode

If a trailing-edge dimmer is detected on the line, the boost converter is operated in trailing-edge dimmer mode. This mode provides dynamic impedance matching for trailing-edge dimmers. The operation can be split into four intervals, as shown in Figure 9.6.

Figure 9.6 : Trailing-Edge Boost Mode Operation

During interval 0, the boost BJT is driven in current sink mode to reset the dimmer with a low impedance load. Interval 1 begins as the  $V_{IN}$  rises above the zero crossing reference. The boost BJT is driven in switching mode to boost energy into the boost output capacitor. Then interval 2 starts at a short period of time before the phase-cut edge to increase the switching duty cycle as a transition state between interval 1 and interval 3. Interval 3 begins right at the phase-cut edge. The boost BJT switches with four times of the duty cycle as in interval 1 to quickly discharge the EMI capacitor inside the dimmer so as to ensure the accurate phase.

### 9.3.3 No Dimmer Mode (PFC Operation)

If there is no dimmer on the line, boost converter is operated in PFC mode for optimal power factor and minimum harmonic distortion. The iW3617 switches the boost BJT in valley mode switching to minimize the switching loss and EMI. Input current will follow the input voltage as shown in Figure 9.7.

Figure 9.7 : No Dimmer Boost Mode Operation

The iW3617's PFC algorithm is based on fixed on-time switching with the compensation of dead-time after the boost inductor resets. The dead-time is measured from the moment that boost inductor resets (determined by  $BV_{SENSE}$ ).

pin) to the following boost BJT turn-on moment (determined by  $B_{DRV}$  pin). To maximize the power efficiency, the boost output capacitor voltage is set to be 30V above the peak AC line voltage for 230V AC input and 15V above for 120V AC input.

### 9.3.4 Transition Between Operation Modes

The iW3617 constantly monitors the derivative of the  $V_{IN}$  signal every AC half cycles to ensure the boost converter's operation is in the correct mode. The mode of the operation is continuously updated based on the latest detected dimmer type.

The iW3617 also monitors dimmer existence by looking at the D ratio. If the D ratio is greater than 90% at any time, the boost converter will enter the No Dimmer mode immediately.

## 9.4 LED Current Regulation and Dimming Control Block Operation

This section provides information about iW3617 LED current regulation and dimming control block operation.

### 9.4.1 Cycle-by-Cycle LED Current Regulation

The LED current regulation and dimming control block incorporates the iWatt-patented PrimAccurate™ technology. Constant current is guaranteed regardless of the input voltage (boost output capacitor voltage) or the output voltage (LED load forward voltage) of the flyback converter. Figure 9.8 shows the basic principle of this constant current regulation algorithm.

Figure 9.8 : Constant Current Regulation

The flyback converter is operated in critical discontinuous conduction mode (CDCM). When the flyback MOSFET (Q1 in Figure 11.1) turns on, the transformer primary winding

current ramps up linearly and energy builds up in the transformer. The iW3617 turns off the MOSFET when the primary winding current reaches the peak current regulation level. At this moment, the transformer maintains the magnetic flux so that the energy in the transformer generates the secondary winding current that equals to the peak primary winding current multiplied by primary-secondary turns-ratio. Then the secondary winding current ramps down linearly until all the energy in transformer is discharged. After the energy in the transformer is discharged, the iW3617 starts the next switching cycle. The LED load current is the average of the saw-tooth shaped secondary winding current.

The LED load current can be determined by an equation as shown below.

$$I_{OUT} = 0.5 \times N_{TR} \times I_{PK} \times T_R / T_P \quad (9.2)$$

where  $I_{PK}$  is the peak of primary winding current.  $N_{TR}$  is the primary-secondary turns ratio.  $T_R$  is the secondary winding current ramp-down time, or the transformer reset time.  $T_P$  is the entire switching period.

The  $I_{PK}$  is determined by the voltage generated on the current-sense resistor:  $I_{PK} = V_{PK} / R_S$ . Therefore, the equation can be written as:

$$I_{OUT} = 0.5 \times N_{TR} / R_S \times (V_{PK} \times T_R / T_P) \quad (9.3)$$

The iW3617 measures  $T_R$  and  $T_P$  on a cycle-by-cycle basis and controls  $V_{PK}$  so that the  $K_{CC} = V_{PK} \times T_R / T_P$  is always a constant. The  $K_{CC}$  is an internally defined constant that equals to 0.7V. Therefore, the  $I_{OUT}$  can be determined by the turns-ratio and current sense resistor at the design time of the application circuit.

### 9.4.2 Dimming Control

iW3617 has two dimming scheme options which can be selected by the CFG pin (refer to Section 9.5 for details). The first one is pulse width modulation (PWM) dimming. The second one is constant current pulse frequency modulation (CC-PFM) dimming.

- PWM Dimming Mode

From 100% to 25% dimming percentage, the iW3617 employs the same constant current regulation algorithm as described in section 9.4.1 while reducing the  $K_{CC}$  constant. As a result, the  $I_{OUT}$  will proportionally decrease as the  $K_{CC}$  decreases. In this process, the switching frequency of the flyback converter will increase. The maximum switching frequency is clamped at 200kHz.

At 25% dimming percentage, the iW3617 will clamp the  $K_{CC}$  value and switch to the 630Hz PWM dimming. Further

# iW3617

## AC/DC Digital Power Controller for High Power Factor Dimmable LED Drivers

dimming is achieved by only activating the flyback converter during a certain percentage of time in every 630Hz period.

- CC-PFM Dimming Mode

From 100% to 25% dimming percentage, the iW3617 operates in the same  $K_{CC}$ -reduction dimming method as described in PWM dimming, except that the frequency clamp changes linearly from 200kHz at 100% dimming percentage to 50kHz at 25% dimming percentage. Below 25% dimming percentage, the iW3617 will switch to the CC-PFM mode, which keeps the  $V_{PK}$  a constant and increase the  $T_p$  to achieve further dimming.

### 9.5 CFG Pin

The CFG pin is used to select between the two dimming modes (described in Section 9.42) and the two dimming curves (see Figure 10.6). At startup, the CFG pin outputs  $I_{CFG}$  after  $V_{CC}$  reaches  $V_{CC(ST)}$ . The iW3617 reads the CFG pin voltage after 40 $\mu$ s. The dimming curve and dimming mode are selected by connecting a resistor with different values to the CFG pin as shown in Table 9.1

CFG Option Number	CFG Pin Resistor		Dimming Curve Number (Fig. 10.6)	Dimming Control
	Value	Tolerance		
1	20k $\Omega$	$\leq 5\%$	1	PWM
2	12.7k $\Omega$	$\leq 5\%$	1	CC-PFM
3	8.87k $\Omega$	$\leq 5\%$	2	PWM
4	5.62k $\Omega$	$\leq 5\%$	2	CC-PFM

Table 9.1 CFG Pin Resistor

### 9.6 Protection Features

This section provides information about iW3617 protection features.

#### 9.6.1 Output Over-Voltage/LED Open Protection

The iW3617 includes a function that protects against an output over-voltage.

The output voltage is monitored by the  $FV_{SENSE}$  pin. The ratio between the  $FV_{SENSE}$  pin voltage and output voltage is equal to the transformer auxiliary to secondary winding turns-ratio multiplied by the  $FV_{SENSE}$  resistor divider ratio ( $R_{20}$ ,  $R_{21}$  in Figure 11.1). If the voltage at the  $FV_{SENSE}$  pin exceeds  $V_{SENSE(MAX)}$ , the iW3617 shuts down immediately. After the shutdown, the iW3617 remains powered which discharges the  $V_{CC}$ . In order to avoid over-charging the output voltage,

the iW3617 employs an extended discharge time as described below.

Under the fault condition, the iW3617 tries to start up for three consecutive times. If all three start-up attempts fail, the iW3617 enters the inactive mode, during which the iW3617 does not respond to the  $V_{CC}$  power-on requests. The iW3617 is activated again after it sees 29 start-up attempts. The iW3617 can also be reset to the initial condition if the  $V_{CC}$  is completely discharged. Typically, this extended discharge time is around three to five seconds, and it allows the iW3617 to support hot-plug LED modules without causing output over-voltage while maintaining a quick recovery.

#### 9.6.2 Output Short Protection

The iW3617 includes a function that protects against an output short-circuit fault.

If the voltage at the  $FV_{SENSE}$  pin is below 0.228V, the iW3617 shuts down immediately. After the shutdown, the iW3617 remains powered, which discharges the  $V_{CC}$ . In order to avoid excessive power stress due to auto-restart, the iW3617 employs an extended discharge time (as described in Section 9.61).

To support applications with high output capacitance, output short protection is not activated in the initial LED current soft start period. This allows the voltage to build up in the output capacitor without mis-triggering the protection.

#### 9.6.3 Over-Temperature Protection

If an NTC thermistor is connected between the  $V_T$  pin and the GND, the iW3617 is able to detect and protect against an over-temperature event.

The iW3617 provides an  $I_{VT}$  to the  $V_T$  pin and detects the voltage on the pin. Based on this voltage, the iW3617 can monitor the resistance of the NTC thermistor, which is related to the temperature of the thermistor. As the  $V_T$  pin voltage reduces, the iW3617 reduces the power in boost and flyback converter.

Figure 9.9 :  $V_T$  Pin Voltage vs. % of Nominal Output Current

When the  $V_T$  pin voltage reaches  $V_{P-LIM(HI)}$  the output current begins to reduce linearly from 100% to 20% as shown in Figure 9.9. At  $V_{P-LIM(LO)}$  the output current will be clamped to 1%. If the  $V_T$  pin voltage further decreases to below  $V_{SH\_TH}$ , the iW3617 will shut down.

The iW3617 will remain in shut-down mode as long as the  $V_T$  pin voltage is below  $V_{SH\_TH}$ . If the  $V_T$  pin voltage rises above  $V_{SH\_TH}$  at any time, the device will start up and the output will be clamped at 1%. Once the  $V_T$  pin voltage reaches  $V_{P-LIM(LO)}$ , the output current will increase to 20%. From  $V_{P-LIM(LO)}$  to  $V_{P-LIM(HI)}$ , the output current will increase linearly from 20% to 100% as shown in Figure 9.9. Finally, the device will go back to normal operation when the  $V_T$  pin voltage rises above  $V_{P-LIM(HI)}$ .

This bi-directional operation of the  $V_T$  pin enables the LED current thermal foldback instead of an abrupt shut-down of the light. As the output power decreases under the mild over-temperature condition, the amount of heat generated by the LED also decreases, which reduces the possibility of further temperature rise of the system.

### 9.6.4 Over-Current Protection

Over-current protection (OCP) is a feature that is built into the iW3617.

With the  $FI_{SENSE}$  pin the iW3617 is able to monitor the primary peak current of the flyback converter. This allows for cycle-by-cycle peak current control and limit. When the primary peak current multiplied by the  $FI_{SENSE}$  sense resistor ( $R_{15}$  in Figure 11.1) is greater than  $V_{OCP(FLYBACK)}$ , over-current is detected and the iW3617 immediately turns off the gate drive until the next cycle. The  $F_{DRV}$  pin sends out switching pulse in the next cycle, and the switching pulse continues if the  $V_{OCP(FLYBACK)}$  is not reached; or, the switching pulse turns off again if the  $V_{OCP(FLYBACK)}$  is still reached.

The  $BI_{SENSE}$  pin provides the same protection mechanism for the boost converter. The  $BI_{SENSE}$  OCP threshold is  $V_{OCP(BOOST)}$  in no dimmer or trailing-edge dimmer mode. The  $BI_{SENSE}$  OCP threshold is 1.5V in leading-edge dimmer mode.

### 9.6.5 Sense Resistor Short Protection

If the  $FI_{SENSE}$  sense resistor is shorted there is a potential danger of the over-current condition not being detected. Thus the iW3617 is designed to detect this sense-resistor short fault. If the voltage on the  $FI_{SENSE}$  pin is below  $V_{RS(FLYBACK)}$  after 15.6 $\mu$ s of turning on, the sense-resistor short protection is triggered and the iW3617 shuts down immediately. After the shutdown, the  $V_{CC}$  is discharged since the iW3617 remains powered. The iW3617 employs an extended discharge time (as described in Section 9.61) before restart.

If the  $BI_{SENSE}$  resistor is shorted, the iW3617 cannot determine the emitter current of the boost BJT, which can ultimately result in the boost BJT exceeding its safe operating area. Thus the iW3617 is designed to detect this boost sense-resistor short fault. When the iW3617 detects a boost-sense-resistor short fault at the detection cycle, the iW3617 shuts down immediately. In the leading-edge and trailing-edge modes, the detection cycle is the zero crossing period in an AC half cycle. If there is no dimmer on the line, the only detection cycle is at start-up. After the shutdown, the  $V_{CC}$  is discharged since the iW3617 remains powered. To prevent over-stress on the boost circuit components, the iW3617 employs an extended discharge time (as described in Section 9.61) before restart.

### 9.6.6 Boost Inductor Short-Protection

The boost inductor is protected from short condition in no dimmer mode. If the  $BV_{SENSE}$  pin is not able to see the reset of the boost inductor, the boost inductor short is detected. The iW3617 will short down immediately.

### 9.6.7 AC Input and Boost Output Over-Voltage Protection

The iW3617 supports the over-voltage protection of AC input and boost output voltage.

If the  $V_{IN}$  pin voltage is higher than  $V_{IN\_OVP}$  for continuous 2ms within every 16ms period, and this condition lasts for eight consecutive AC half cycles, the iW3617 shuts down both the boost and flyback converters. After the shutdown, the  $V_{CC}$  is discharged since the iW3617 remains powered. When  $V_{CC}$  drops below  $V_{CC(UVL)}$ , the iW3617 resets itself and then initiates a new soft-start cycle.

---

If the  $V_{CB}$  pin voltage is higher than  $V_{CB\_OVP}$  for continuous 128ms, then the iW3617 shuts down both the boost and flyback converters. After the shutdown, the  $V_{CC}$  is discharged since the iW3617 remains powered. When  $V_{CC}$  drops below  $V_{CC(UVL)}$ , the iW3617 resets itself and then initiates a new start cycle.

Under both the input and boost output over-voltage fault condition, the iW3617 employs an extended discharge time (as described in Section 9.61) before restart.

### 12.0 Physical Dimensions

14-Lead SOIC Package

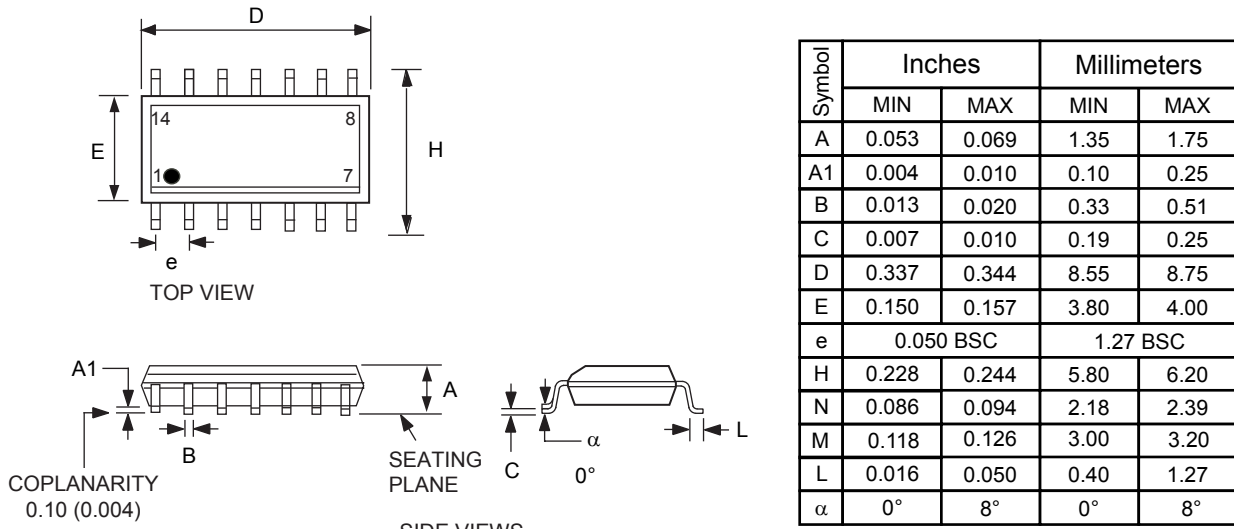

Figure 12.1 : Physical dimensions, 8-lead SOIC package

Compliant to JEDEC Standard MS12F

Controlling dimensions are in inches; millimeter dimensions are for reference only

This product is RoHS compliant and Halide free.

Soldering Temperature Resistance:

[a] Package is IPC/JEDEC Std 020D Moisture Sensitivity Level 1

[b] Package exceeds JEDEC Std No. 22-A111 for Solder Immersion Resistance; package can withstand 10 s immersion < 270°C

Dimension D does not include mold flash, protrusions or gate burrs. Mold flash, protrusions or gate burrs shall not exceed 0.15 mm per end. Dimension E does not include interlead flash or protrusion. Interlead flash or protrusion shall not exceed 0.25 mm per side.

The package top may be smaller than the package bottom. Dimensions D and E are determined at the outermost extremes of the plastic body exclusive of mold flash, tie bar burrs, gate burrs and interlead flash, but including any mismatch between the top and bottom of the plastic body.

### 13.0 Ordering Information

Part Number	Options	Package	Description
iW3617-00	120V <sub>AC</sub> Input	SOIC-14	Tape & Reel <sup>1</sup>
iW3617-01	230V <sub>AC</sub> Input	SOIC-14	Tape & Reel <sup>1</sup>

Note 1: Tape & Reel packing quantity is 2,500/reel.
