## Design Example Report

|  | Two-Wire (No Neutral), Wide Range <br> Input, Bluetooth Wall Switch with Relay <br> Zero-Voltage Switching and Automatic <br> Set/Reset Time Calibration using <br> LinkSwitch |
| :--- | :--- |
| SpecifinZ LNK3302D |  |$|$

## Summary and Features

- Compatible with 2-wire (no neutral), home / building wiring
- Relay zero-voltage switching with automatic set time calibration at start-up
- Non-isolated LNK3302D power supply with half-wave rectifier
- Low-component count with integrated 725 V MOSFET, current-sensing, and protection
- Wide-range AC input
- 3 W to 500 W resistive load, 5 to 150 W LED load
- $<150 \mu \mathrm{~A}$ standby current (including BLE) at 230 VAC

## PATENT INFORMATION

The products and applications illustrated herein (including transformer construction and circuits external to the products) may be covered by one or more U.S. and foreign patents, or potentially by pending U.S. and foreign patent applications assigned to Power Integrations. A complete list of Power Integrations' patents may be found at www.power.com. Power Integrations grants its customers a license under certain patent rights as set forth at https://www.power.com/company/intellectual-propertylicensing/.

## Important Note:

Although this board is designed to satisfy safety isolation requirements, the engineering prototype has not been agency approved. Therefore, all testing should be performed using an isolation transformer to provide the AC input to the prototype board.

## 1 Introduction

A typical smart wall switch requires LINE and NEUTRAL to properly work. This is true especially on many WIFI-based switches that consume higher power. However, a majority of homes around the world do not have a neutral wire on the wall switch. A two-wire (no Neutral) smart wall switch addresses this market.

One of the challenges in making a two-wire switch is the need to minimize leakage current that might cause 'ghosting' or light flutter even when the switch is OFF. Many bulbs, especially the non-dimmable types, do not have a bleeder circuit that prevents 'ghosting' due to high leakage current. Minimizing the leakage current ensures wider compatibility across many types of load.

Another challenge is the need to switch the relay exactly at the zero crossing to eliminate high in-rush current. However, when considering different set and reset times for relays and their respective tolerances, it is difficult to design a smart switch that dynamically knows the set time and reset time of the actual relay used. Without knowing these delays, the relay can't be switched at zero crossing of input line.

This report addresses both challenges using the LinkSwitch-TNZ, paired with a proprietary current-shaping circuit for ultra-low current consumption. With the ZCD signal coming from the LinkSwitch-TNZ IC, relay set time and reset time can be known during one-time startup calibration. The relay can now be switched at zero crossing even if the user requests for an asynchronous turn-on via the app or physical switch. With this solution, alternate relays with varying set and reset times can be used interchangeably and still switch at zero-crossing. Specifically, this report can calibrate up to one-line period of set time variation.

This document is an engineering report describing a two-wire (no Neutral) Bluetooth lowenergy (BLE) smart wall switch using LinkSwitch-TNZ LNK3302D. This demo board is intended as a general purpose evaluation platform for LinkSwitch-TNZ.

The document contains the power supply specification, schematic, bill of materials, transformer documentation, printed circuit board layout, and performance data.

## 3 Schematic

Figure 3 - Schematic.

Figure 4 - Block Diagram Schematic.

## 4 Circuit Description

### 4.1 LinkSwitch-TNZ Block

### 4.1.1 Input Stage

The input stage is comprised of fuse F1 for safety protection, varistor RV1 for up to 500 V differential line surge protection, half-wave bridge rectifier diode D2, and bulk capacitor C1.

### 4.1.2 Current-Shaping Circuit

The proprietary R-Z circuit R1 and VR1 form a simple, yet effective means to improve the power factor of the circuit. A higher PF will result to the lowest standby input current. Resistor R1 reduces the peak input current which effectively reduces the input RMS current and increases the power factor. Zener diode VR1 connected in parallel with R1 provides the charging path for the bulk capacitor C 1 during start-up to be able to operate the circuit properly. Please see appendix A for tips on how to choose the optimum values for R1 and VR1.

### 4.1.3 LinkSwitch-TNZ Circuit Operation

LinkSwitch-TNZ LNK3302D was configured in a non-isolated flyback topology to be able to have a fixed reference ground for both the converter and the microcontroller. This configuration allows relay to be turned on and turned off at zero crossing through processing the ZCD signal from LNK3302D IC. The flyback circuit is formed by the main controller LNK3302D U1, transformer T1, bulk capacitor C1, secondary diode D1 and capacitor C 14 . The BP pin capacitor C 5 , with a value of 100 nF , sets the current limit to standard mode.

### 4.1.4 Primary Bias Supply

A 12 V auxiliary supply was taken from the bias winding of T1, rectified by D3 and C6. It provides external biasing of the BP pin through R26. The value of R26 was tuned to provide the lowest no-load input current by setting the BP current slightly higher than Is1. Since the auxiliary winding is just a "slave" winding, there could be some part-to-part variation on the auxiliary voltage that may cause the BP current to deviate from its ideal supply current. If tighter control of BP current is desired, then a simple constant current circuit using a transistor and a Zener may be added.

### 4.1.5 Feedback

Output regulation is achieved through resistor divider formed by R5 and R7 to set the output voltage. Capacitor C16 provides decoupling and stability compensation to prevent overshoot during start-up or load step.

### 4.2 Low Drop-Out Regulator Block

The LDO regulator U7 provides a stable 3 V supply for the BLE module and relay RL1. Capacitor C 15 is the output capacitor of U7. A $560 \mu \mathrm{~F}$ was used to sustain the power drawn by the relay during its transition period of $10-20 \mathrm{~ms}$. When the relay is OFF, the input to the LDO comes from LinkSwitch-TNZ. When the relay is ON, the supply comes from Q1 regulator via D10 and R18.

### 4.3 Relay Circuit Block

A 3 V, 2-coil, latching relay RL1 from Panasonic (ADW1203HL) was used. Unlike conventional relay, latching type retains its last state even when the power is gone, similar to that of a regular wall switch. Moreover, it only requires a 3 V pulse of about 10 ms to set and reset the relay unlike conventional relay that needs steady supply.

Transistor Q4, R19, R20 drive the relay OFF while Q5, R21, R22 drive the relay ON. Diodes D11 and D12 protect the transistors Q4 and Q5 from 'inductive kick' by clamping the voltage to 3 V plus 1 diode drop.

### 4.4 Q1 Regulator Circuit Block (Power Supply when the Relay is ON)

This DER uses low voltage MOSFET Q1 and gate driver circuit using a comparator U6.
When the relay is ON, the FET Q1 gate is initially OFF. Depending on the phase of the input line, current may flow from the Source to Drain through Q1 body diode or D7 if the AC line phase is more positive than neutral. In the negative-going phase, since Q1 is OFF, then current will flow through D8 and D9 and will charge the capacitors C12, C13 and C14. The output of comparator U 6 is kept low until the voltage on its (+) input equals the reference (-) input which was set to 3 V . The 7.5 V Zener VR3 provides the voltage threshold that determines when the comparator will change state. The threshold is given by $\mathrm{Vz}(7.5 \mathrm{~V})+\mathrm{Vref}(3 \mathrm{~V})=10.5 \mathrm{~V}$. Resistor R17 provides the bias for the Zener and is also responsible for the R-C timer formed by R17 and C12. A $1 \%$ tolerance resistor is recommended for R17 and C12 should be of NPO/COG type.

Once the threshold has been reached, the comparator will change from LOW to HIGH state, driving Q1 ON. The circuit comprised of R14, R15, R16 and Q3 provide hysteresis (from 3 V to 1.8 V reference) to prevent Q1 from rapidly turning ON and OFF and is also part of the R-C timer circuit.

The time constant formed by R17 and C12 was selected such that once Q1 turns ON, it will remain ON for about 32.4 ms . This time could be computed using the equation below:

$$
\begin{gathered}
t_{Q 1 \_o n}=-R C * \ln \left(\frac{V_{\text {ref_1.8V }}}{V_{\text {ref_3V }}}\right) \\
t_{Q 1 \_o n}=-(634 k)(100 \mathrm{n}) * \ln \left(\frac{1.8}{3}\right)=32.4 \mathrm{~ms}
\end{gathered}
$$

The choice of 32.4 ms is chosen to ensure that the regulator will work properly for both 50 Hz and 60 Hz system. The ON-time may be adjusted on a single input system (voltage, frequency). In selecting the ON time, the goal is to maximize the time that Q1 is ON, and make sure that it turns OFF when the current is flowing in the direction from the Source to Drain (LINE IN more positive than LINE OUT). Diode D7 is connected in parallel with Q1 so that the current will not flow through Q1 body diode after the FET turns OFF. To minimize the dissipation on D7, the ON-time can be set as close as possible to the input voltage zero-crossing. However, enough margin must be maintained due to component tolerances that affects the timing.

The ON time of Q1 was optimized at 60 Hz system and not on 50 Hz system. Due to this, the dissipation on D7 is higher on 50 Hz system since Q1 ON time was not maximized. To minimize the dissipation on D7 for both 50 Hz and 60 Hz system, circuit comprising R24, R11, and Q2, provides a bypass turn off function to the output of the comparator U6 to control when to turn off Q1. Hence, ON time of Q1 can now be maximized since delay to turn off Q1 can be controlled by the microcontroller using the ZCD signal from the LinkSwitch-TNZ. The ZCD_OUT signal from the microcontroller is configured to turn off Q1 every 14 ms delay for a 60 Hz system and 18 ms delay for a 50 Hz system.

Resistor R13 is the pull-up resistor for the output of the comparator U6.

The regulator circuit used in this DER has some restrictions:
a. There is a minimum load required to operate the switch properly. Unlike conventional wall switch with line and neutral, the bulb load is required to close the power loop. If the load is too small, it presents a high impedance or open-circuit; hence, the BLE switch will not work.
b. It is not advisable to use smart bulbs with the wall switch. When the smart bulb is remotely turned OFF, for example, it usually goes into low-power mode and the BLE switch might stop working because the load drops below the minimum load requirement.

### 4.5 Bluetooth Low Energy (BLE) Module Circuit Block

This DER uses a Bluetooth 5-certified Bluetooth Low Energy (BLE) module U4, MDBT42Q, based on Nordic NRF52832 SoC. Its ultra-low current consumption, together with LinkSwitch-TNZ power supply, enables a < $150 \mu \mathrm{~A}$ standby input current at 230 VAC.

### 4.5.1 Pin Functions

| Pin Number | Description |
| :---: | :--- |
| 4 (P0.27) | Configured as Digital Input. This pin detects low-to-high transition interrupt or toggle <br> interrupt from the ZCD_IN signal. |
| 15 (P0.02) | Configured as ADC Input. The pin detects the relay state by sensing the voltage across <br> VR2. Resistor R9 provides the bias current for the Zener. |
| 31 (P0.17) | Configured as Digital Input. Senses the push-button switch SW1 to trigger relay <br> ON/OFF. C9 provides passive de-bouncing to ensure clean input signal when the switch <br> SW1 is pressed. |
| 32 (P0.18) | Configured as Digital Output. Provides a 20 ms pulse to turn OFF the latching relay. |
| 33 (P0.19) | Configured as Digital Output. Provides a 10 ms pulse to turn ON the latching relay. |
| 27 (P0.13) | Configured as Digital Output. Provides a $100 ~ \mu \mathrm{~s} \mathrm{pulse} \mathrm{(ZCD} \mathrm{\_OUT} \mathrm{signal)} \mathrm{to} \mathrm{turn} \mathrm{OFF}$ <br> the output of comparator U6. |
| 36 (SWDCLK) | Programming pin. |
| 37 (SWDIO) | Programming pin. |
| 11 (VDD) | The VDD comes from the 3V LDO regulator. C7 is the VDD filter capacitor while D4 <br> protects the BLE module from negative voltage. |

Table 1 - Bluetooth Module Pin Description.

### 4.5.2 Using the App

This DER uses a Nordic based application, nRF Blinky, for its BLE functionality.
Step 1: Power-up the BLE wall switch.
Step 2: Install nRF Blinky App on Android or IOS devices that support Bluetooth 4.0 or higher.

Figure 5 - nRF Blinky Application.

Step 3: Switch-ON Bluetooth on the mobile device.

Step 4: Open the nRF Blinky App, the app should detect "DER 867"

Figure 6 - DER-867 on nRF Blinky App.

Step 5: Select DER-867 to connect to unit. Once connected, LED and Button interface can be seen.

## 5 Firmware Block Diagram

This DER uses the following algorithm to detect the inherent relay set time and relay reset time of the relay through the zero crossing signal from the LinkSwitch-TNZ LNK3302D.

Figure 9 - Firmware Block Diagram.

### 5.1 Initialization

Initialization starts on the onset of unit power-up through the line. During power-up the following peripherals needs to be initialized for algorithm to properly work: GPIO, Timers, Bluetooth communication, Interrupts.

### 5.2 ADC Start-up Check

After initialization, power must be stable before beginning any operation at the microcontroller. This code block ensures that the relay is turned off by throwing a relay off signal then implementing a 500 ms delay before enabling ZCD interrupt for Line Frequency Check state.

### 5.3 Line Frequency Check

After ZCD interrupt has been enabled, this state identifies the line frequency based on the ZCD signal. This correctly identifies whether input voltage is operating at 60 Hz or 50 Hz frequency. Once line frequency has been identified, ZCD interrupt will be disabled for 100 ms before proceeding to the Relay ON Timing Check state.

### 5.4 Relay ON Timing Check

After ZCD interrupt has been enabled again, the algorithm will wait for a high-to-low (HITOLO) transition from the ZCD signal. Once transition has been determined, a timer will immediately start and a switch on signal will be sent to the relay driver circuit to turn on the relay. Due to the inherent set time of the relay, the relay will not switch on immediately. Consequently, ZCD signal remains low during this delay. Once the relay is on, ZCD signal will toggle to high. This will signal the microcontroller to stop the timer and store the relay set time delay determined from the timer.

Set RELAY_ON.
Start timer. Stop timer

HIGH

## ZCD SIGNAL

HIGH

LOW

Figure 10 - Determining Relay Set Time During the $1^{\text {st }}$ Pulse Calibration.

The relay set time will then be check if it is below half line period. If it is below the half line period, it will proceed to the Relay Off Timing Check state. Otherwise, the relay has not turned on yet since relay set time might be greater than half line period or relay turned on at exactly at half line period.

To address this, a $2^{\text {nd }}$ pulse start-up calibration will be fired but this time instead of waiting for a HITOLO transition from the ZCD signal, LOTOHI transition will be the interrupt. Similar from the $1^{\text {st }}$ pulse start-up calibration, timer will start when there is a LOTOHI transition and will stop when there is a $2^{\text {nd }}$ LOTOHI transition toggle in the ZCD signal because it is the indication that the relay successfully latches.

Figure 11 - Determining Relay Set Time During the $2^{\text {nd }}$ Pulse Calibration.

Once relay set time has been determined from either the $1^{\text {st }}$ pulse start-up calibration or $2^{\text {nd }}$ pulse start-up calibration, it will proceed to the Relay OFF Timing Check state.

### 5.5 Relay OFF Timing Check

Once relay set time has been stored, relay off time will be determined in this code block. The ZCD state handler from the microcontroller will now only detect LOTOHI transitions. Once a LOTOHI transition has been determined, there will be a one period delay before sending signal to set relay off. The timer will start after the relay off signal was sent and will stop when a LOTOHI interrupt has been registered. After relay off delay has been stored, ZCD interrupt handler will be disabled and the relay set time and reset time has been configured.

Figure 12 - Determining Relay Reset Time.

### 5.6 Turn-On State and Turn-Off State

Once turn on delay and turn off delay has been configured to switch the relay at zero crossing. The microcontroller waits for user input either through Bluetooth app (NRF Blinky) or through on-board button. Depending on the relay status, the code switches between Turn on state and Turn off state.

For switching on the relay, the following equation will be the delay to include the turn on delay/set time to switch at zero crossing:

$$
\text { turn_on_delay }=\text { linePeriod }- \text { relaySetTime }
$$

For switching off the relay, the following equation will be the delay to include the turn off delay/reset time to switch at zero crossing:

$$
\text { turn_off_delay }=2 * \text { linePeriod }- \text { relayOFF_delay }
$$

## 6 PCB Layout

PCB specifications:

- Layer count: 2 layers
- Solder mask: Green
- Silkscreen: White
- Finish: LF HASL
- Board Thickness: 1.6 mm
- Copper Thickness: 2 oz. (2.8 mils)
- Material: FR4

## 10 Performance Data

All measurements performed at room temperature. Unless otherwise stated, the test data refers to system-level performance.

### 10.1 Standby Input Leakage Current

Standby current was measured when the relay is OFF. A 500 W incandescent bulb was connected between Line Out and Neutral to complete the circuit loop. The leakage current, even with BLE connected, was kept below $200 \mu \mathrm{~A}$ at worst-case input voltage. At 230 VAC, the leakage current was below $150 \mu \mathrm{~A}$.

Figure 17 - Standby Input Current.

### 10.2 LinkSwitch-TNZ Leakage Current vs. System-Level Leakage Current

The leakage current contribution of the LinkSwitch-TNZ power supply was taken by disconnecting the LDO regulator from the circuit. System input current measurements were taken after adding the 3 V regulator and the BLE module.

Figure 18 - LinkSwitch-TNZ Leakage Current vs. System Leakage.

### 10.3 LinkSwitch-TNZ Regulation vs. Load on 3 V Output, Relay OFF

The non-isolated flyback design using LinkSwitch-TNZ LNK3302D is rated for $3.5 \mathrm{~V}, 60 \mathrm{~mA}$ output. Actual current capability increases as the input voltage increases as shown in the graph below.

Figure 19 - LinkSwitch-TNZ Regulation vs. Load on 3 V Output.

### 10.4 Maximum Continuous Load on 3 V Regulator Output, Relay ON

Supply comes from the Q1 FET regulator.
The MOSFET Q1 regulator current capability is dependent on the characteristic of the load connected to the AC line. This is because the charging current needed to charge the capacitor that supplies power to the 3 V LDO regulator is limited by the current being drawn by the bulb load.

If this reference design is used on other wireless module, then the maximum load that the FET regulator can supply is shown on Figure 20. Also, as the 3 V load goes up, it is necessary to reduce or even short R18, increase C13, C14, and C15, as well as use a higher current-rated 3 V linear regulator.

Figure 20 - Maximum Continuous Load on 3 V Regulator Output vs. Resistive Load (Connected to AC Line).

## 11 Waveforms

### 11.1 Inrush Current Comparison with and without Zero Crossing Detection

### 11.1.1 50 W Synthetic Low Power Factor Load (PF = 0.5)

Tested at $120 \mathrm{VAC}, 60 \mathrm{~Hz}$. The synthetic low power factor load used is based on NEMA SSL 7A-2013.
Inrush current reduced by about 45 A on subsequent power-up.

Figure 21 - Without using ZCD, $1^{\text {st }}$ Power-up, 120 VAC, $60 \mathrm{~Hz}, 50 \mathrm{~W} 0.5$ PF Synthetic Load.

CH 1 : Input Voltage, $100 \mathrm{~V} /$ div.

$I_{\text {PEAK }}=3.49 \mathrm{~A}$.

### 11.2 Zero Crossing Switching Waveforms using Incandescent Load

To demonstrate the automatic set time calibration at start-up, the unit must be able to calibrate with no hardware and no firmware modification if the relay is changed to a different relay. Table 2 describes the specification of the three different relays used for this test.

| Specification | ADW1203HLW (DER default relay) | ST1-L2-DC3V-F | DSP1A-L2-DC3V |
| :---: | :---: | :---: | :---: |
| Contact arrangement | 1 Form A | 1 Form A 1 Form B | 1 Form A |
| Operating function | 2 coil latching | 2 coil latching | 2 coil latching |
| Rated coil voltage <br> (DC) | 3 V | 3 V | 3 V |
| Contact Rating (resistive) | Inrush type (16A, Inrush current $100 \mathrm{~A})$ | 8 A 250 V AC, 5 A 30 V DC | 8 A 250 V AC, 5 A 30 V DC |
| Max. switching voltage | 277 VAC | 250 V AC, 30 V DC | 250 V AC, 125 V DC (0.2A) |
| Max. switching current | 16 A (AC) | $8 \mathrm{~A}(\mathrm{AC}), 5 \mathrm{~A}$ (DC) | $8 \mathrm{~A}(\mathrm{AC}), 5 \mathrm{~A}$ (DC) |
| Operate (Set) time | Max. 15 ms at rated coil voltage (without bounce) | Max. 15 ms (Max. 15 ms ) at rated coil voltage (at $20^{\circ} \mathrm{C}$, without bounce) | Max. 10 ms (Max. 10 ms ) at rated coil voltage (at $20^{\circ} \mathrm{C}$, without bounce) |
|  | Measured set time $=4 \mathrm{~ms}$ | Measured set time $=8.2 \mathrm{~ms}$ | Measured set time $=5 \mathrm{~ms}$ |
| Release (Reset) time | Max. 15 ms at rated coil voltage (without bounce) | Max. 10 ms (Max. 15 ms ) at rated coil voltage (at $20^{\circ} \mathrm{C}$, without bounce, without diode) | Max. 5 ms (Max. 10 ms ) at rated coil voltage (at $20^{\circ} \mathrm{C}$, without bounce, without diode) |
|  | Measured reset time, max $=9 \mathrm{~ms}$ | Measured reset time, max $=9 \mathrm{~ms}$ | $\begin{aligned} & \text { Measured reset time, max }= \\ & 8.7 \mathrm{~ms} \end{aligned}$ |
| Contact material | AgSnO2 type | Au-flashed $\mathrm{AgSnO}_{2}$ type | Au-flashed $\mathrm{AgSnO}_{2}$ type |

Table 2 - Specification of the Two Relay Used.

### 11.2.1 Using ADW1203HLW - Switching ON Relay (Measured Relay Set Time = 4 ms )

Figure 33 - Set Time Calibration (1 pulse), 120 VAC, $60 \mathrm{~Hz}, 190$ W Incandescent Load, Using ADW1203HLW.

### 12.2 Thermals, Relay OFF

When the relay is OFF, the power supply comes from the LinkSwitch-TNZ circuit. The thermal data, however, was taken using simulated load on the 3 V output to verify the performance if the same design will be used on higher power design up to its rated limit.

Figure 102 - Bottom, 90 VAC, 60 Hz. Load: 3 V, 60 mA.

## 13 Conducted EMI

Conducted EMI was tested when the relay is OFF. This was to check the emission of LinkSwitch-TNZ IC only. When the relay is ON, LinkSwitch-TNZ IC does not switch anymore and only the Q1 regulator is operational. Since the regulator switches every AC line cycle, it is possibly to get worse EMI than when a bulb is directly connected to the line. However, this response is analogous to a typical TRIAC dimmer that 'chops' the line voltage and causes incident emission which is acceptable as per FCC part 15 standard. Hence, this DER does not address EMI issue that may arise due to the Q1 regulator.

## 14 Line Surge Testing

The unit was subjected to $\pm 2500 \mathrm{~V}, 100 \mathrm{kHz}$ ring wave and $\pm 500 \mathrm{~V}$ differential surge with 10 strikes at each condition. A test failure was defined as a non-recoverable interruption of output requiring repair or recycling of input voltage. The test was done with the relay in OFF position, and with an incandescent bulb to close the circuit loop.

## 15 Appendix A - Current-Shaping Circuit Optimization

The proprietary current-shaping circuit using R1 and VR1 improves the power factor of the circuit, which results to lower standby input current. The optimized value to maximize PF depends on the amount of load that is being drawn by the circuit. In this DER, since the overall system consumption is very low, then a value of $100 \mathrm{k} \Omega$ can be used. The Zener voltage was set to 12 V so that LinkSwitch-TNZ IC would still operate properly even if the available bulk voltage on C 1 is reduced by 12 V .

If the system current consumption is higher, such as when using different wireless module with higher standby current, then the value of R1 needs to be re-tuned accordingly. Maximum PF can be achieved by setting the resistor value such that the voltage across the resistor is slightly below the Zener voltage. Figure 123 shows the graph of recommended R1 value for various 3 V load current.

Figure 123 - Recommended R1 Value for Various Load on the 3 V Regulator.
